(57) **ABSTRACT**

An apparatus for communicating content includes an image capturing module that captures a rendering of at least a portion of a first still image. The first still image includes a shot from a sequence of images of a video. The first still image includes an embedded cryptographic representation of a code. The code corresponds to the sequence of still images comprising the video. The apparatus includes a decoding module that decodes the embedded cryptographic representation of the code to identify the code, a content retrieval module that retrieves the sequence of still images of the video corresponding to the code, and a display module that displays the sequence of still images of the video. A first displayed shot of the video includes the first still image and a remainder of the video includes a remaining series of images from the sequence of images of the video displayed in chronological order.

**DISPLAYING VIDEO RETRIEVED FROM  
EMBEDDED CODE IN A STILL IMAGE****CROSS-REFERENCES TO RELATED  
APPLICATIONS**

This application is a continuation application of and claims priority to U.S. patent application Ser. No. 13/899,502 entitled "EMBEDDING INFORMATION IN AN IMAGE" and filed on May 21, 2013 for Rene Rodriguez Marchant, which claims the benefit of U.S. Provisional Patent Application No. 61/649,446 entitled "APPARATUS, SYSTEM, AND METHOD FOR EMBEDDING INFORMATION IN AN IMAGE" and filed on May 21, 2012, and which are herein incorporated by reference. U.S. patent application Ser. No. 13/900,422 entitled "DISPLAYING CONTENT ASSOCIATED WITH CODE EMBEDDED IN AN IMAGE" and filed on May 22, 2013 for Rene Rodriguez Marchant, and U.S. patent application Ser. No. 13/900,466 entitled "CAPTURING VIDEO OF AN IMAGE WITH EMBEDDED CODE TO ACCESS CONTENT" and filed on May 22, 2013 for Rene Rodriguez Marchant, are incorporated herein by reference.

**FIELD**

This invention relates to displaying content associated with information embedded in an image and more particularly relates to capturing a rendering of a still image with an embedded code and retrieving a sequence of images associated with the code.

**BACKGROUND**

Advertising has changed dramatically in a short period of time. The internet has brought new advertising methods and consumers are moving away from traditional print and television advertising. Social media has brought new avenues of advertising as well. As a result, consumers often look to the internet for information about a product before buying. Even when consumers visit a brick and mortar store, they often use a mobile electronic device, such as a smartphone or tablet computer to seek more information. Increasingly consumers are looking for videos for information about a product or service rather than taking time to read text. Videos about products have increased dramatically, but vendors continue to struggle to distinguish their products over millions of other products and websites.

**SUMMARY**

An apparatus for communicating content is disclosed. A method and a computer program product also perform the functions of the apparatus. The apparatus includes an image capturing module that captures a rendering of at least a portion of a first still image. The first still image includes a shot from a sequence of images of a video. The first still image includes an embedded cryptographic representation of a code. The code corresponds to the sequence of still images comprising the video. The apparatus includes a decoding module that decodes the embedded cryptographic representation of the code to identify the code, a content retrieval module that retrieves the sequence of still images of the video corresponding to the code, and a display module that displays the sequence of still images of the video. A first displayed shot of the video includes the first still image and a remainder of

2

the video includes a remaining series of images from the sequence of images of the video displayed in chronological order.

In one embodiment, the display module automatically displays the sequence of still images of the video in response to the decoding module decoding the embedded cryptographic representation of the code and the content retrieval module retrieving the sequence of still images of the video corresponding to the code. In another embodiment, each cryptographic representation of each character of the code includes a group of regularly spaced mark locations. Each mark location has a mark selected from a nonnative mark or a native mark. A pattern of marks in the group of regularly spaced mark locations is unique to each character in the code. In another embodiment, the apparatus includes an orientation module that determines an orientation of the rendering of the at least a portion of the still image. Orientation of the rendering of the at least a portion of the still image is determined by comparing a distance between mark locations in a first group of regularly spaced mark locations with a distance between mark locations in a second group of regularly spaced mark locations. In another embodiment, the orientation of the rendering of at least a portion of the still image is determined in three dimensions.

In one embodiment, the nonnative mark includes a marking added to the still image. The marking has a perceptible difference between a native intensity value of a location in the still image and an intensity value of the marking added to the still image. In a further embodiment, the perceptible difference between the native intensity value of the location in the still image and the intensity value of the marking added to the still image includes a difference that is greater than a predefined threshold.

In one embodiment, the image capturing module captures an environment surrounding the at least a portion of the still image and the display module displays the environment surrounding the at least a portion of the still image. The sequence of still images is superimposed on the environment surrounding the at least a portion of the still image. In another embodiment, the display module changes the displayed orientation of the sequence of still images in response to the orientation module determining that the orientation of the rendering of at least a portion of the still image has changed. In another embodiment, the apparatus includes a mobile device where the mobile device includes the image capturing module, the decoding module, the content retrieval module, and the display module.

A method for communicating content includes capturing a rendering of at least a portion of a first still image. The first still image includes a shot from a sequence of images of a video and the first still image includes an embedded cryptographic representation of a code. The code corresponds to the sequence of still images comprising the video. The method includes decoding the embedded cryptographic representation of the code to identify the code, retrieving the sequence of still images of the video corresponding to the code, and displaying the sequence of still images of the video. A first displayed shot of the video includes the first still image and a remainder of the video includes a remaining series of images from the sequence of images of the video displayed in chronological order.

In one embodiment, displaying the sequence of still images of the video includes automatically displaying the sequence of still images of the video in response to decoding the embedded cryptographic representation of the code and retrieving the sequence of still images of the video corresponding to the code. In another embodiment, each crypto-

3

graphic representation of each character of the code includes a group of regularly spaced mark locations, each mark location having a mark selected from a nonnative mark or a native mark. A pattern of marks in the group of regularly spaced mark locations is unique to each character in the code. The method, in one embodiment, includes determining an orientation of the rendering of the at least a portion of the still image. In another embodiment, orientation of the rendering of the at least a portion of the still image is determined by comparing a distance between mark locations in a first group of regularly spaced mark locations with a distance between mark locations in a second group of regularly spaced mark locations.

In another embodiment, displaying the sequence of still images of the video changes the displayed orientation of the sequence of still images in response to determining that the orientation of the rendering of at least a portion of the still image has changed. In another embodiment, the nonnative mark includes a marking added to the still image. The marking has a perceptible difference between a native intensity value of a location in the still image and an intensity value of the marking added to the still image. In another embodiment, capturing a rendering of at least a portion of a first still image comprises capturing an environment surrounding the at least a portion of the still image. Displaying the sequence of still images of the video includes displaying the environment surrounding the at least a portion of the still image. In another embodiment, the method is part of a computer program product for displaying content. The computer program product includes a computer readable storage medium having program code embodied therein.

### BRIEF DESCRIPTION OF THE DRAWINGS

In order that the advantages of the invention will be readily understood, a more particular description of the invention briefly described above will be rendered by reference to specific embodiments that are illustrated in the appended drawings. Understanding that these drawings depict only typical embodiments of the invention and are not therefore to be considered to be limiting of its scope, the invention will be described and explained with additional specificity and detail through the use of the accompanying drawings, in which:

FIG. 1 is a schematic block diagram illustrating one embodiment of a system 100 to embed information in an image in accordance with the present invention;

FIG. 2 is a schematic block diagram illustrating one embodiment of a code definition module in accordance with the present invention;

FIG. 3A is a schematic block diagram illustrating one embodiment of a cryptography module in accordance with the present invention;

FIG. 3B is a schematic block diagram illustrating one embodiment of a cryptographic representation of a character in accordance with the present invention;

FIG. 4 is a schematic block diagram illustrating one embodiment of a cryptography system in accordance with the present invention;

FIG. 5 is a schematic block diagram illustrating another embodiment of a cryptography module in accordance with the present invention;

FIG. 6 is a schematic block diagram illustrating one embodiment of an embedding module in accordance with the present invention;

4

FIG. 7A is a schematic block diagram depicting one embodiment of an orientation module for determining an orientation of an image with the image substantially perpendicular to an image viewer;

FIG. 7B illustrates a schematic block depicting an embodiment of an orientation module for determining an orientation of an image wherein the image is rotated about an y-axis with respect to an image viewer;

FIG. 7C illustrates a schematic block depicting an embodiment of an orientation module for determining an orientation of an image wherein the image is rotated about an x-axis with respect to an image viewer;

FIG. 8 is a schematic block diagram illustrating one embodiment of an apparatus to communicate content in accordance with the present invention;

FIG. 9A is a schematic block diagram illustrating one embodiment of an operation of an orientation module and a display module for determining a first orientation of the embedded image and displaying a unit of content in an orientation corresponding to the first orientation in accordance with the present invention;

FIG. 9B is a schematic block diagram illustrating one embodiment of an operation of an orientation module and a display module for determining a second orientation of the embedded image and displaying a unit of content in an orientation corresponding to the second orientation in accordance with the present invention;

FIG. 10 is a schematic block diagram illustrating one embodiment of an operation of an image capturing module and a display module for superimposing a unit of content on a capture of an environment surrounding an image in accordance with the present invention;

FIG. 11 is a schematic block diagram illustrating one embodiment of an apparatus to communicate content in accordance with the present invention;

FIG. 12 is a schematic block diagram illustrating one embodiment of an apparatus to communicate content in accordance with the present invention;

FIG. 13 is a schematic flowchart diagram illustrating one embodiment of a method of embedding information in an image in accordance with the present invention;

FIG. 14 is a schematic flowchart diagram illustrating one embodiment of a method to communicate content in accordance with the present invention;

FIG. 15 is a schematic flowchart diagram illustrating one embodiment of a method to capture live video of an image with embedded code to access and communicate content in accordance with the present invention; and

FIG. 16 is a schematic flowchart diagram illustrating one embodiment of a method to capture a rendering of a still image with embedded code to access and communicate a sequence of related still images in accordance with the present invention.

### DETAILED DESCRIPTION

Reference throughout this specification to “one embodiment,” “an embodiment,” or similar language means that a particular feature, structure, or characteristic described in connection with the embodiment is included in at least one embodiment. Thus, appearances of the phrases “in one embodiment,” “in an embodiment,” and similar language throughout this specification may, but do not necessarily, all refer to the same embodiment, but mean “one or more but not all embodiments” unless expressly specified otherwise. The terms “including,” “comprising,” “having,” and variations thereof mean “including but not limited to” unless expressly

5

specified otherwise. An enumerated listing of items does not imply that any or all of the items are mutually exclusive and/or mutually inclusive, unless expressly specified otherwise. The terms “a,” “an,” and “the” also refer to “one or more” unless expressly specified otherwise.

Furthermore, the described features, advantages, and characteristics of the embodiments may be combined in any suitable manner. One skilled in the relevant art will recognize that the embodiments may be practiced without one or more of the specific features or advantages of a particular embodiment. In other instances, additional features and advantages may be recognized in certain embodiments that may not be present in all embodiments.

These features and advantages of the embodiments will become more fully apparent from the following description and appended claims, or may be learned by the practice of embodiments as set forth hereinafter. As will be appreciated by one skilled in the art, aspects of the present invention may be embodied as a system, method, and/or computer program product. Accordingly, aspects of the present invention may take the form of an entirely hardware embodiment, an entirely software embodiment (including firmware, resident software, micro-code, etc.) or an embodiment combining software and hardware aspects that may all generally be referred to herein as a “circuit,” “module,” or “system.” Furthermore, aspects of the present invention may take the form of a computer program product embodied in one or more computer readable medium(s) having program code embodied thereon.

Many of the functional units described in this specification have been labeled as modules, in order to more particularly emphasize their implementation independence. For example, a module may be implemented as a hardware circuit comprising custom VLSI circuits or gate arrays, off-the-shelf semiconductors such as logic chips, transistors, or other discrete components. A module may also be implemented in programmable hardware devices such as field programmable gate arrays, programmable array logic, programmable logic devices or the like.

Modules may also be implemented in software for execution by various types of processors. An identified module of program code may, for instance, comprise one or more physical or logical blocks of computer instructions which may, for instance, be organized as an object, procedure, or function. Nevertheless, the executables of an identified module need not be physically located together, but may comprise disparate instructions stored in different locations which, when joined logically together, comprise the module and achieve the stated purpose for the module.

Indeed, a module of program code may be a single instruction, or many instructions, and may even be distributed over several different code segments, among different programs, and across several memory devices. Similarly, operational data may be identified and illustrated herein within modules, and may be embodied in any suitable form and organized within any suitable type of data structure. The operational data may be collected as a single data set, or may be distributed over different locations including over different storage devices, and may exist, at least partially, merely as electronic signals on a system or network. Where a module or portions of a module are implemented in software, the program code may be stored and/or propagated on in one or more computer readable medium(s).

The computer readable medium may be a tangible computer readable storage medium storing the program code. The computer readable storage medium may be, for example, but not limited to, an electronic, magnetic, optical, electromag-

6

netic, infrared, holographic, micromechanical, or semiconductor system, apparatus, or device, or any suitable combination of the foregoing.

More specific examples of the computer readable storage medium may include but are not limited to a portable computer diskette, a hard disk, a random access memory (RAM), a read-only memory (ROM), an erasable programmable read-only memory (EPROM or Flash memory), a portable compact disc read-only memory (CD-ROM), a digital versatile disc (DVD), an optical storage device, a magnetic storage device, a holographic storage medium, a micromechanical storage device, or any suitable combination of the foregoing. In the context of this document, a computer readable storage medium may be any tangible medium that can contain, and/or store program code for use by and/or in connection with an instruction execution system, apparatus, or device.

The computer readable medium may also be a computer readable signal medium. A computer readable signal medium may include a propagated data signal with program code embodied therein, for example, in baseband or as part of a carrier wave. Such a propagated signal may take any of a variety of forms, including, but not limited to, electrical, electro-magnetic, magnetic, optical, or any suitable combination thereof. A computer readable signal medium may be any computer readable medium that is not a computer readable storage medium and that can communicate, propagate, or transport program code for use by or in connection with an instruction execution system, apparatus, or device. Program code embodied on a computer readable signal medium may be transmitted using any appropriate medium, including but not limited to wire-line, optical fiber, Radio Frequency (RF), or the like, or any suitable combination of the foregoing.

In one embodiment, the computer readable medium may comprise a combination of one or more computer readable storage mediums and one or more computer readable signal mediums. For example, program code may be both propagated as an electro-magnetic signal through a fiber optic cable for execution by a processor and stored on RAM storage device for execution by the processor.

Program code for carrying out operations for aspects of the present invention may be written in any combination of one or more programming languages, including an object oriented programming language such as Java, Smalltalk, C++, PHP or the like and conventional procedural programming languages, such as the “C” programming language or similar programming languages. The program code may execute entirely on the user’s computer, partly on the user’s computer, as a stand-alone software package, partly on the user’s computer and partly on a remote computer or entirely on the remote computer or server. In the latter scenario, the remote computer may be connected to the user’s computer through any type of network, including a local area network (LAN) or a wide area network (WAN), or the connection may be made to an external computer (for example, through the Internet using an Internet Service Provider).

The computer program product may be integrated into a client, server and network environment by providing for the computer program product to coexist with applications, operating systems and network operating systems software and then installing the computer program product on the clients and servers in the environment where the computer program product will function.

Furthermore, the described features, structures, or characteristics of the embodiments may be combined in any suitable manner. In the following description, numerous specific details are provided, such as examples of programming, software modules, user selections, network transactions, data-

base queries, database structures, hardware modules, hardware circuits, hardware chips, etc., to provide a thorough understanding of embodiments. One skilled in the relevant art will recognize, however, that embodiments may be practiced without one or more of the specific details, or with other methods, components, materials, and so forth. In other instances, well-known structures, materials, or operations are not shown or described in detail to avoid obscuring aspects of an embodiment.

Aspects of the embodiments are described below with reference to schematic flowchart diagrams and/or schematic block diagrams of methods, apparatuses, systems, and computer program products according to embodiments of the invention. It will be understood that each block of the schematic flowchart diagrams and/or schematic block diagrams, and combinations of blocks in the schematic flowchart diagrams and/or schematic block diagrams, can be implemented by program code. The program code may be provided to a processor of a general purpose computer, special purpose computer, sequencer, or other programmable data processing apparatus to produce a machine, such that the instructions, which execute via the processor of the computer or other programmable data processing apparatus, create means for implementing the functions/acts specified in the schematic flowchart diagrams and/or schematic block diagrams block or blocks.

The program code may also be stored in a computer readable medium that can direct a computer, other programmable data processing apparatus, or other devices to function in a particular manner, such that the instructions stored in the computer readable medium produce an article of manufacture including instructions which implement the function/act specified in the schematic flowchart diagrams and/or schematic block diagrams block or blocks.

The program code may also be loaded onto a computer, other programmable data processing apparatus, or other devices to cause a series of operational steps to be performed on the computer, other programmable apparatus or other devices to produce a computer implemented process such that the program code which executed on the computer or other programmable apparatus provide processes for implementing the functions/acts specified in the flowchart and/or block diagram block or blocks.

The schematic flowchart diagrams and/or schematic block diagrams in the Figures illustrate the architecture, functionality, and operation of possible implementations of apparatuses, systems, methods and computer program products according to various embodiments of the present invention. In this regard, each block in the schematic flowchart diagrams and/or schematic block diagrams may represent a module, segment, or portion of code, which comprises one or more executable instructions of the program code for implementing the specified logical function(s).

It should also be noted that, in some alternative implementations, the functions noted in the block may occur out of the order noted in the Figures. For example, two blocks shown in succession may, in fact, be executed substantially concurrently, or the blocks may sometimes be executed in the reverse order, depending upon the functionality involved. Other steps and methods may be conceived that are equivalent in function, logic, or effect to one or more blocks, or portions thereof, of the illustrated Figures.

Although various arrow types and line types may be employed in the flowchart and/or block diagrams, they are understood not to limit the scope of the corresponding embodiments. Indeed, some arrows or other connectors may be used to indicate only the logical flow of the depicted

embodiment. For instance, an arrow may indicate a waiting or monitoring period of unspecified duration between enumerated steps of the depicted embodiment. It will also be noted that each block of the block diagrams and/or flowchart diagrams, and combinations of blocks in the block diagrams and/or flowchart diagrams, can be implemented by special purpose hardware-based systems that perform the specified functions or acts, or combinations of special purpose hardware and program code.

FIG. 1 illustrates a schematic block diagram of a system 100 to embed information in an image according to one embodiment of the present invention. The system 100 includes a computer 102 having a code definition module 104, a cryptography module 106, an embedding module 108, and an orientation module 109. In certain embodiments the system 100 also includes a computer network 110, a file server 112, a number of work stations such as work stations 114 and 116, a display unit 118, a mobile computing device 120, and a printer 122.

While the embodiment illustrated in FIG. 1 shows the code definition module 104, the cryptography module 106, the embedding module 108, and the orientation module 109 as being stored on a computer 102, one skilled in the art will recognize that the code definition module 104, the cryptography module 106, the embedding module 108, and the orientation module 109 may be contained within a file server 112, a mainframe, a personal computer, a laptop, a personal digital assistant, or other computing device. The computer 102 and the file server 112 are connected to the computer network 110 providing remote access to the code definition module 104, the cryptography module 106, the embedding module 108, and the orientation module 109 via a computer network 110.

The code definition module 104, the cryptography module 106, the embedding module 108, and the orientation module 109 may be accessed directly through input/output devices connected to the computer 102 or through the computer network 110 in a client-server relationship, remote access, or other network-related operation. One of skill in the art will recognize other ways to access the code definition module 104, the cryptography module 106, the embedding module 108, and the orientation module 109.

In one embodiment, the code definition module 104, the cryptography module 106, the embedding module 108, and the orientation module 109 are stored on a data storage device in or connected to a computer 102. In another embodiment, the code definition module 104, the cryptography module 106, the embedding module 108, and the orientation module 109 may be distributed in different locations throughout the system 100. In certain embodiments the code definition module 104 may be stored on one device within the system 100 and the cryptography module 106, the embedding module 108, and the orientation module 109 may be stored other devices within the system 100. One of skill in the art will recognize other ways to store and execute portions of the code definition module 104, the cryptography module 106, the embedding module 108, and the orientation module 109.

As further discussed below, in certain embodiments, the system 100 may include a display unit 118, a mobile computing device 120, and/or a printer 122 for displaying an image having embedded information therein. In certain embodiments, the display unit 118 may be a standalone display such as a monitor or a television. In one embodiment, the embedded image, having embedded cryptographic representations, may be displayed on a mobile computing device 120 such as a conventional cellular phone, a Smartphone, a Personal Data Assistant (PDA), a tablet computer, etc. In other

embodiments, the embedded image may be printed on a printer **122** such as a convention dot matrix printer, laser printer, etc. One of skill in the art will recognize other ways of displaying the embedded image.

FIG. 2 is a schematic block diagram illustrating one embodiment of a code definition module **104** in accordance with the present invention. In certain embodiments, the code definition module **104** defines a code **202** corresponding to a unit of content **204**. The unit of content **204**, in one embodiment, may be any digital information relayable to a user. For example, in one embodiment, the unit of content may be a two or three dimensional image **206** uniquely linked to or referenced by the code **202**. In other embodiment, the unit of content **204** may be a Uniform Resource Locator (URL) directing a user to a webpage **210** uniquely linked to or referenced by the code **202**. In yet another embodiment, the unit of content may be a two or three dimensional video image **208** uniquely linked to or referenced by the code **202**. One of skill in the art will recognize other units of content **204** (i.e. informational units) that may be linked to or referenced by the code **202**.

In certain embodiments, the units of content **204** referenced by or linked to the code **202** may be stored on the computer **102**, the file server **112**, the mobile device, or on any of the work stations **114-116**. In such an embodiment, the units of information may reside or be stored within the system **100**. In other embodiments, the units of content **204** may reside or be stored on a remote device or system (not shown).

The code **202**, in certain embodiments, includes at least one character **212**. In certain embodiments, the characters **212** defining the code **202** are unique to a particular unit of content. In other embodiments, the characters **212** may be unique to a number of units of content **204**. For example, in certain embodiments, the code **202** may be linked to or reference one or more still image **206**, one or more video image **208** and/or one or more webpages **210**.

The characters **212** comprising the code **202**, in one embodiment, are an alphanumeric character. For example, in certain embodiments, each character **212** may be any numeral from zero (0) through nine (9) and/or an alphabet character from A through F. Thus, in one embodiment, the code may contain various arrangements of the sixteen different characters **212**. One of skill in the art will recognize that in other embodiments, the characters **212** may be non-alphanumeric characters. Similarly, one of skill in the art will recognize that in certain embodiments, the code **202** may include additional alphabet characters other than the characters A through F.

The characters **212** are arranged to create an identifier unique to one or more units of content **204**. In one embodiment, the code includes twelve characters **212**. For example, in the embodiment illustrated in FIG. 1, the code **202** includes the characters "F, 9, 8, C, D, 5, A, 5, 6, 0, 4, and A." This code **202** may be unique to a particular unit of content **204**, i.e., video image **208**. Thus, as further discussed below, when a particular image includes an embedded code "F98CD5A5604A" the code **202** may be used to retrieve the video image **208** corresponding to that code **202**. Of course, other codes **202** will have a different arrangement of characters **212** that identify different units of content **204**.

In one embodiment, the code **202** includes a start identifier **214**, a payload section **216**, an error check section **218**, and a stop identifier **220**. In certain embodiments, only the payload section **216** is unique to a particular unit of content **204**. In such an embodiment, the start identifier **214** may be the same character for every code **202** defined by the code definition module **104**. Similarly, the stop identifier **220** may be the same character for every code **202** defined by the code defi-

nition module **104**. For example, in the embodiment illustrated in FIG. 2, the start identifier **214** is an "F" character **212** and the stop identifier **220** is an "A" character **212**. Any other codes **202** defined by the code definition module **104** will have an "F" as the start identifier **214** and an "A" as the stop identifier **220**. One of skill in the art will recognize that in certain embodiments, the start identifier **214** and the stop identifier **220** may be a character **212** other than an "F" and an "A" respectively.

In other embodiments, the start identifier **214** and the stop identifier **220** may be different for each code **202**. Thus, in one embodiment, the start identifier **214** for one code **202** may be a character **212** i.e., a "C," for another code **202** the start identifier **214** may be a "D," for another code **202** the start identifier may be a "0," etc. Similarly, in certain embodiments, the stop identifier **220** for one code may be a character **212** i.e., a "9," for another code **202** the stop identifier **220** may be an "F," for another code **202** the stop identifier **220** may be an "E," etc.

The payload section **216** is unique to a particular unit of content **204**. In certain embodiments, the payload section **216** includes eight (8) characters **212**. A payload section **216** having eight (8) characters **212** selected from a sixteen (16) possible characters **212** gives four billion two hundred ninety four million nine hundred sixty seven thousand two hundred and ninety six (4,294,967,296) possible arrangements of the characters. Accordingly, if the payload section **216** is limited to eight (8) characters **212**, the code definition module **104** can uniquely define a code for four billion two hundred ninety four million nine hundred sixty seven thousand two hundred and ninety six (4,294,967,296) units of content **204**. In embodiments where this number is insufficient, the payload section **216** of the code **202** can be increased to include more characters **212**.

In certain embodiments, each unit of content **204** is correlated to a particular code **202** through a database **222** that includes a listing of codes **224** and a listing of information units **226** corresponding to the codes. As further discussed below, when a code **202** is identified in an image, the database **222** is referenced to determine which unit of content **204** corresponds to that code **202**.

Given the large number of possible arrangements of the characters **212** in the code **202**, in certain embodiments, the code **202** may include an error check section **218** for checking the payload section **216** of the code **202** to determine the reliability of the payload section **216** of the code **202**. The error check section **218** of the code **202**, in one embodiment, includes a fixed number of characters **212** derived from an algorithm. The listing of information units **226** in the database **222** also includes error check characters **228**. The algorithm used to derive the characters **212** in the error check section **218** of the code **202** is the same algorithm used to derive the error check characters **228** in the listing of information units **226**. When a code **202** is identified in an image, the algorithm is used to determine if characters **212** in the error check section **218** of the code **202** and the error check characters **228** in the listing of the information units **226** match. If the characters **212** in the error check section **218** of the code **202** and the error check characters **228** in the listing of the information units **226** match, the code **202** can be verified as a correct code **202**. If the characters **212** in the error check section **218** of the code **202** and the error check characters **228** in the listing of the information units **226** do not match, the identified code **202** in the image is incorrect and the image should be rechecked or rescanned to determine a correct code **202**.

FIG. 3 is a schematic block diagram illustrating one embodiment of a cryptography module **106** in accordance

with the present invention. In certain embodiments, the cryptography module 106 defines a cryptographic representation 302 for each character 212 of the at least one character 212 in the code 202.

FIG. 3B illustrates an enlarged schematic block diagram of a cryptographic representation 302c of a character 212. Each cryptographic representation 302 is a group of regularly spaced mark locations 304. Thus, a distance between mark location 304a and mark location 304b as illustrated by line 306a is approximately the same as a distance between mark location 304c and mark location 304d as illustrated by line 306b. Similarly, a distance between mark location 304a and mark location 304c as illustrated by line 306c is approximately the same as a distance between mark location 304c and mark location 304d as illustrated by line 306d. In certain embodiments, each mark location 304 is equidistant from at least two mark locations 304. For example, in one embodiment, distances 306a, 306b, 306c and 306d are substantially equal. As further discussed below, an array of regularly spaced mark locations 304 allows an orientation of an image having imbedded cryptographic representations 302 to be determined.

In certain embodiments, each mark location 304 includes a either a nonnative mark 308a or a native mark 308b-308d. A nonnative mark 308a is a marking added to an image that has a perceptible difference between a native intensity value of a location in the image and an intensity value of the marking added to the image. A native mark 308b-308d is a marking having an intensity value substantially similar to a native intensity value of a location in the image corresponding to a particular mark location 304. That is, a native mark 308b-308d has the same intensity value in a particular area as the original unaltered image. For example, in the embodiment illustrated in FIG. 3B, mark locations 304b-304d have native or unaltered markings 308b-308d such that the intensity values for mark locations 304b-304d is substantially the same as the intensity values for the areas in the original unaltered image. Mark location 304a, on the other hand, includes a nonnative mark 308a. Thus, mark location 304a includes a marking that has a perceptible difference between the native intensity of the original image and the marking added to mark location 304a.

In certain embodiments, the perceptible difference for a nonnative mark 308a may be a difference between the native intensity value of the location in the image and the intensity value of the marking added to the image that is greater than a predefined threshold. In such an embodiment, the predefined threshold may be varied to optimize recognition of the intensity difference. In another embodiment, the predefined threshold may be varied as a tradeoff between distortion of the image (i.e., markings observable by the naked eye) and recognition of the markings by a computer implemented process. In yet another embodiment, the predefined threshold may be a maximum difference between the native intensity value of the location in the image and the intensity value of the marking added to the image.

In the embodiment illustrated in FIG. 3B, the native mark locations 304b-304d are illustrated as having a dashed line surrounding each mark location 304b-304d. One of skill in the art will recognize that the dashed line is for illustrative purposes. Accordingly, in certain embodiments, the native mark locations 304b-304d may simply have native markings (i.e., markings that occur in the native image). In other embodiments, the native mark locations 304b-304d may include a marking (such as the dashed lines). Additionally, the embodiment illustrated in FIG. 3B depicts the markings as being circular. However, one of skill in the art will recognize

that in other embodiments, the markings may be square, rectangular, triangular, octagonal, or any other geometric shape.

A pattern of marks in the group of regularly spaced mark locations 304 is unique to each character 212 in the code 202. For example, FIG. 4 depicts a schematic block diagram illustrating one embodiment of a cryptography system 400 in accordance with the present invention. As discussed above, in certain embodiments, the cryptography module 106 defines a cryptographic representation 302 for each character 212 of the at least one character in the code 202. In the embodiment illustrated in FIG. 4, each cryptographic representation 302 (FIG. 3A) includes a group or regularly spaced mark locations 304 (FIG. 3B) and each mark location has a mark selected from one of a nonnative mark 308a (FIG. 3B) and a native mark 308b-308d (FIG. 3b). Each pattern in a group of regularly spaced mark locations 304 is unique to each character 202 of the at least one character in the code 202.

Accordingly, as illustrated in FIG. 4, each of the groups of regularly spaced mark locations 302 has a unique pattern. For example, the pattern of marks for the group of regularly spaced mark locations 304 for the cryptographic representation 302 corresponding to the letter "A" includes nonnative marks 308a in the two leftmost mark locations 304 and native marks 308b-308d in the two rightmost mark locations 304. The pattern of marks for the group of regularly spaced mark locations 304 for the cryptographic representation 302 corresponding to the numeral "1" includes nonnative marks 308a in the two rightmost mark locations 304 and native marks 308b-308d in the two leftmost mark locations 304. Each of the pattern of marks for the group of regularly spaced mark locations 304 for the cryptographic representation 302 corresponding to the other numeric or alphabetic characters have unique patterns of nonnative marks 308a and native marks 308b-308d.

While the cryptography system 400 illustrates six (6) alphabetic characters corresponding to the letters "A-F" and ten numeric characters corresponding to the numerals "0-9," one of skill in the art will recognize that in other embodiments, the cryptography system 400 may have other alphabetic, numeric, or other characters capable of distinguishing a unit of content 204 (FIG. 2).

In the cryptography system 400 illustrated in FIG. 4, there are sixteen (16) total permutations of mark patterns in the groups of regularly spaced mark locations 304. The sixteen (16) permutations include every possible permutation for groups of mark locations 304 having four (4) possible variations of marks in four (4) possible mark locations 304. However, one of skill in the art will recognize that in certain embodiments, the cryptography system 400 may include more than sixteen (16) total characters 212. In such an embodiment, the groups of regularly spaced mark locations 304 may include more than four (4) mark locations 304 to accommodate additional variations of marks.

FIG. 5 is a schematic block diagram illustrating another embodiment of a cryptography module 106 in accordance with the present invention. As discussed above, in certain embodiments, the cryptography module 106 defines a cryptographic representation 504 for each character 212 of the at least one character in the code 202, each cryptographic representation comprising a group 504 of regularly spaced mark locations 304 (FIG. 3B). As discussed above, in certain embodiments, only the nonnative marks 308a are added to an image at an appropriate mark location 304. In such an embodiment, the native marks 308b-308d are simply the native intensity values of the original image.

13

In certain embodiments, the group's 504 of regularly spaced mark locations 304 are positioned in a number of rows and columns. In one embodiment, the group's 504 of regularly spaced mark locations 304 are positioned in four rows and three columns. In other embodiments, the group's 504 of regularly spaced mark locations 304 may be positioned in more rows and columns. In yet another embodiment, the group's 504 of regularly spaced mark locations 304 are positioned in fewer rows and columns.

In the embodiment illustrated in FIG. 5, the patterns of marks in the groups 504 of regularly spaced mark locations 304 correspond to characters 212 in the code 202. Thus, character 212a, an "F" corresponds to the pattern of marks in the group 504a of regularly spaced mark locations 304. Similarly, character 212b, a "9" corresponds to the pattern of marks in the group 504b of regularly spaced mark locations 304. In this manner, each of the other characters 212c-212i in the code 202 is represented by the other group's 504c-504i.

As discussed above, the first character 212a typically represents a start indicator. Thus, the pattern of marks in group 504a corresponds to a start indicator, in this case a representation of the character "F" 212a. The last character 212i typically represents a stop indicator. Accordingly, the pattern of marks in group 504i corresponds to a stop indicator, in this case a representation of the character "A" 212i. The pattern of marks in groups 504j and 504k correspond to the error check section 218 (FIG. 2) of the code 202.

In the embodiment illustrated in FIG. 5, the group's 504 of regularly spaced mark locations 304 are shown as having a dashed line surrounding each group 504. One of skill in the art will recognize that the dashed lines are depicted for illustrative purposes and that in actual use, the dashed lines may be omitted.

FIG. 6 is a schematic block diagram illustrating one embodiment of an embedding module 108 in accordance with the present invention. In certain embodiments, the embedding module 108 embeds the cryptographic representation 302 for each character 212 of the at least one character of the code 202 into at least a portion 604 of an image 602. In certain embodiments, the cryptographic representation 302 of each character 212 may be repeated throughout the image 602 such that the code 202 is redundantly represented throughout the image 602 such that the representation of the code 202 can be identified by scanning any portion of the image. As further discussed below, a distance between mark locations 304 in the image 602 indicates an orientation of the image 602.

In certain embodiments, the embedding module 108 embeds the cryptographic representation 302 for each character 212 of the at least one character of the code 202 into at least a portion 604 of an image 602 by adding a marking to the image 602. In one embodiment, the marking added to the image 602 has a perceptible difference between a native intensity value of a location in the image 602 (the original image intensity) and an intensity value of the marking added to the image 602. In certain embodiments, the perceptible difference between the native intensity value of the location in the image and the intensity value of the marking added to the image may be a difference that is greater than a predefined threshold. In other embodiments, the marking may have a maximum intensity value.

In one embodiment, the markings may be added to a multiple color channels of the image 602. In certain embodiments, the markings are added to a single color channel. In yet another embodiment, the markings are added to the blue color channel. Markings in the blue color channel may provide the least noticeable color variations such that the markings are

14

difficult to perceive by a human and the image 602 having the embedded markings looks substantially similar to the original unembedded image.

FIGS. 7A-7C illustrates various schematic block diagrams depicting embodiments of an orientation module 109 in accordance with the present invention. Specifically, FIG. 7A is a schematic block diagram depicting an embodiment of the orientation module 109 for determining an orientation of an image wherein the image is substantially perpendicular to an image viewer. FIG. 7B illustrates a schematic block depicting an embodiment of the orientation module 109 for determining an orientation of an image wherein the image is rotated about a y-axis with respect to an image viewer. FIG. 7C illustrates a schematic block depicting an embodiment of the orientation module 109 for determining an orientation of an image wherein the image is rotated about an x-axis with respect to an image viewer.

In certain embodiments, as further discussed below, the image viewer may be an image capturing module, such as a flatbed scanner, a digital camera, etc. that captures a rendering of the image 602 or a portion 604 of the image 602 having the groups 504 of regularly spaced mark locations 304 corresponding to the embedded cryptographic representations 302 of the code 202. Where the image 602 or the portion 604 of the image is substantially perpendicular to the image viewer, a distance between each mark locations 304 is approximately the same for all of the groups 504 of regularly spaced mark locations 304 corresponding to the embedded cryptographic representations 302 of the code 202.

For example, with reference to FIG. 7A, when the image 602 or the portion 604 of the image 602 is substantially perpendicular to an image viewer, a horizontal distance 702a between the regularly spaced mark locations 304 of group 504k is approximately the same as a horizontal distance 702b between the regularly spaced mark locations 304 of group 504i. Similarly, a vertical distance 702c between the regularly spaced mark locations 304 of group 504g is approximately the same as a vertical distance 702d between the regularly spaced mark locations 304 of group 504j. Distances between the regularly spaced mark locations 304 of the other group's 504a-504f, 504h, and 504i are also approximately the same.

When the image 602 or the portion 604 of the image 602 is rotated about the y-axis, as illustrated in FIG. 7B, the horizontal distances between the mark locations 304 changes depending on the position of the particular group 504 within the image 602 or portion 604 of the image 602. For example, because of the limitations with respect to depicting an image 602 or portion 604 of an image 602 in two dimensions, mark locations 304 located further away from the image viewer will appear closer together when viewed in two dimensions. Thus, the horizontal distance 702a between the regularly spaced mark locations 304 of group 504k is larger than a horizontal distance 702b between the regularly spaced mark locations 304 of group 504i when the image 602 or portion 604 of the image 602 is viewed in two dimensions. Because the image 602 or portion 604 of the image 602 depicted in FIG. 7B is only rotated about the y-axis, all of the vertical distances between the regularly spaced mark locations 304 of the groups 504 are approximately the same.

When the image 602 or the portion 604 of the image 602 is rotated about the x-axis, as illustrated in FIG. 7C, the vertical distances between the mark locations 304 also changes depending on the position of the particular group 504 within the image 602 or portion 604 of the image 602. Again, because of the limitations with respect to depicting an image 602 or portion 604 of an image 602 in two dimensions, mark

15

locations 304 located further away from the image viewer will appear closer together when viewed in two dimensions. Thus, the vertical distance 702c between the regularly spaced mark locations 304 of group 504j is larger than the vertical distance 702d between the regularly spaced mark locations 304 of group 504g when the image 602 or portion 604 of the image 602 is viewed in two dimensions. Because the image 602 or portion 604 of the image 602 depicted in FIG. 7C is only rotated about the x-axis, all of the horizontal distances between the regularly spaced mark locations 304 of the groups 504 are approximately the same.

While the embodiments discussed above indicate that the orientation module 109 references distances between the mark locations 304 within various groups 504 to determine an orientation of the image 602 or portion 604 of the image 602, one of skill in the art will recognize that the orientation module 109 may use various other visual indicators to determine the orientation of the image 602 or portion 604 of the image 602. For example, in one embodiment, the orientation module 109 may reference a size of the markings within the mark locations 304 of the various groups 504 to determine the orientation of the image 602 or portion 604 of the image 602. Markings located further away from the image viewer will appear smaller than markings located closer to the image viewer.

In certain embodiments, the orientation module 109 of the image 602 or the portion 604 of the image 602 may be determined in three dimensions. For example, in one embodiment, the orientation module 109 may determine a rotation of the image 602 or the portion 604 of the image 602 about the y-axis as discussed above with reference to FIG. 7B. The orientation module 109 may also determine a rotation of the image 602 or the portion 604 of the image 602 about the x-axis as discussed above with reference to FIG. 7C. Determining the rotation of the image 602 or the portion 604 of the image 602 about the z-axis involves simply referencing which direction the groups 504 of regularly spaced mark locations 304 are rotated with respect to the z-axis.

One of skill in the art will recognize other ways of determining an orientation of at least a portion 604 of the image 602. For example, in certain embodiments, the orientation module 109 may use a size of the nonnative markings embedded within the image 602 to determine the orientation of the image 602. If the nonnative markings all have a substantially similar size in an image 602 that is substantially perpendicular to the image viewer, when the image 602 is rotated the nonnative markings that are positioned further away from the image viewer will appear smaller in the two dimensional rendering of the image 602. By comparing the relative sizes of the nonnative markings, the orientation module 109 can determine the orientation of the image 602.

In the embodiments illustrated in FIGS. 7A-7C, the native markings are shown as dashed lines for ease of illustration. However, as discussed above, in an exemplary embodiment, the native markings are simply native to the original image. Accordingly, in certain embodiments, native markings do not include any changes to the original image. Additionally, in FIGS. 7B and 7C reference numerals for mark locations 304 and groups 504 have been omitted for clarity. However, one of skill in the art will recognize that in certain embodiments the portion 604 of the image 602 depicted in FIG. 7A may be substantially similar to the portions 604 of the images 602 depicted in FIGS. 7B and 7C.

FIG. 8 is a schematic block diagram illustrating one embodiment of an apparatus 800 to communicate content in accordance with the present invention. In certain embodiments, the apparatus 800 includes an image capturing module

16

802, a decoding module 804, an orientation module 806, a content retrieval module 808, and a display module 810.

While the embodiment illustrated in FIG. 8 depicts the decoding module 804, the orientation module 806, and the content retrieval module 808 as being stored on a file server 112, one skilled in the art will recognize that the decoding module 804, the orientation module 806, and the content retrieval module 808 may be contained within a mobile computing device 120, mainframe, a personal computer 812, a personal digital assistant, or other computing device.

The mobile computing device 120, personal computer 812 and the file server 112 are connected to the computer network 110 providing remote access to the image capturing module 802 the decoding module 804, the orientation module 806, and the content retrieval module 808 via a computer network 110. The image capturing module 802, decoding module 804, the orientation module 806, and the content retrieval module 808 may be accessed directly through input/output devices connected to the personal computer 812 or the mobile computing device 120. In other embodiments, the image capturing module 802, the decoding module 804, the orientation module 806, and the content retrieval module 808 may be accessed through the computer network 110 in a client-server relationship, remote access, or other network-related operation. One of skill in the art will recognize other ways to access the image capturing module 802, the decoding module 804, the orientation module 806, and the content retrieval module 808.

In one embodiment, the decoding module 804, the orientation module 806, and the content retrieval module 808 are stored on a data storage device in or connected to the personal computer 812 or mobile computing device 120. In another embodiment, the decoding module 804, the orientation module 806, and the content retrieval module 808 may be distributed in different locations throughout the apparatus 800. In certain embodiments the decoding module 804 may be stored on one device within the apparatus 800 and the orientation module 806 and the content retrieval module 808 may be stored on other devices within the apparatus 800. One of skill in the art will recognize other ways to store and execute portions of the decoding module 804, the orientation module 806, and the content retrieval module 808.

The image capturing module 802, in certain embodiments, is a conventional camera or webcam coupled to or integral within one of the mobile computing device 120 or the personal computer 812. The image capturing module 802 captures a rendering of at least a portion of an image. For example, in one embodiment, the image capturing module 802 captures a rendering of the portion 604 of the image 602 discussed above with reference to FIG. 6. In the embodiment illustrated in FIG. 8, the image capturing module 802a is depicted on the same side of the mobile computing device 120 as the display module 810a and the image capturing module 802b is depicted on the same side of the computer 812 as the display module 810b. However, one of skill in the art will recognize that in other embodiments, the display modules 810a and 810b may be positioned on an opposite side of the mobile computing device 120 or the computer 812 respectively.

As discussed above, the image 602 includes an embedded cryptographic representation 302 of at least one character 212 in a code 202. The code 202 corresponds to a unit of content such as the units of content 206, 208, or 210 in FIG. 2. The embedded cryptographic representation 302 of the at least one character 212 in the code 202 identifies an orientation of at least a portion 604 of the image 602 as further discussed below.

17

The decoding module **804** decodes the embedded cryptographic representation **302** of the characters **212** in the code **202**. In certain embodiments, the decoding module **804** uses the cryptography system **400** of FIG. **4** to decode the embedded cryptographic representation **302** of the characters **212** in the code **202**. One of skill in the art will recognize other decoding methods for determining the characters **212** in the code **202**.

In certain embodiments, the orientation module **806** determines an orientation of the rendering of at least a portion **604** of an image **602**. In certain embodiments, the orientation module **806** uses the embedded cryptographic representation **302** of the at least one character **212** in the code **202** to identify the orientation of the portion **604** of the image **602** in a manner substantially similar to the manner in which the orientation module **109** of system **100** determines the orientation of the image **602** as discussed above with reference to FIGS. **7A-7C**.

The content retrieval module **808** retrieves the unit of content **204** (i.e., a unit of content **206**, **208**, or **210**) corresponding to the code **202** from a storage location. In certain embodiments, the storage location may be a storage module located on one of the file server **112**, the mobile computing device **120**, or the computer **812**. In other embodiments, the storage location may be a remote website or other location accessible by the computer network **110**.

The display module **810** displays the unit of content **204** (i.e., a unit of content **206**, **208**, or **210**) on the user's computer **812** or mobile computing device **120**. In certain embodiments, the unit of content **204** (i.e., a unit of content **206**, **208**, or **210**) is displayed in an orientation corresponding to the orientation of the rendering of the at least a portion **604** of the image **602**.

In certain embodiments, the display module **810** changes the displayed orientation of the unit of content **204** (i.e., a unit of content **206**, **208**, or **210**) in response to the orientation module **806** determining that the orientation of the rendering of at least a portion **604** of the image **602** has changed.

For example, FIG. **9A** illustrates a schematic block diagram illustrating one embodiment of an operation **900** of the orientation module **806** and the display module **810a** for determining a first orientation **902** of the embedded image **602** and displaying a unit of content **204** in an orientation **904** corresponding to the first orientation **902** in accordance with the present invention. FIG. **9B** illustrates a schematic block diagram illustrating one embodiment of an operation **910** of the orientation module **806** and the display module **810a** for determining a second orientation **906** of the embedded image **602** and displaying a unit of content **204** in an orientation **908** corresponding to the second orientation **906** in accordance with the present invention.

In FIG. **9A** the image capturing module **802a** has captured a rendering of at least a portion **604** of the image **602**. As discussed above, in certain embodiments, the image capturing module **802a** may capture a rendering of the entire image **602**. In other embodiments, the image capturing module **802a** may only capture rendering of a portion **604** of the image **602**. In such an embodiment, a size of the portion **604** of the image **602** captured by the image capturing module **802a** should be sufficient to contain the embedded cryptographic representations **302** for each character **212** of the at least one character **212** in the code **202**.

In certain embodiments, the orientation module **806** references the position of mark locations **304** (FIG. **3B**) to compare the distances **702** (FIG. **7A-7C**) between the mark locations **304** and determine the orientation (the first orientation **902** as illustrated in FIG. **9A**) of the image **602**. In other

18

embodiments, the orientation module **806** compares the size of nonnative markings in the mark locations **304** to determine the orientation (the first orientation **902** as illustrated in FIG. **9A**) of the image **602**.

The display module **810a** uses the orientation (the first orientation **902** as illustrated in FIG. **9A**) of the image **602**, as determined by the orientation module **806**, to display the unit of content **204** in an orientation **904** corresponding to the orientation (the first orientation **902** as illustrated in FIG. **9A**) of the image **602**. In the embodiment illustrated in FIGS. **9A** and **9B**, the unit of content **204** is illustrated as a video image **208**. One of skill in the art will recognize that in other embodiments, the unit of content **204** may be any other information type communicable to a user via digital communication.

If the orientation of the image **602** changes, as illustrated in FIG. **9B**, the image capturing module **802a** captures a rendering of the image **602** or a portion **604** of the image **602** in the changed orientation. Thus, if the orientation of the image **602** changes from the first orientation **902**, as illustrated in FIG. **9A**, to a second orientation **908**, as illustrated in FIG. **9B**, the image capturing module **802a** captures a rendering of the image **602** or a portion **604** of the image **602** in the changed orientation. In certain embodiments, the image capturing module **802a** continuously or repeatedly captures renderings of the image **602** or a portion **604** of the image **602** as the orientation of the image **602** is the changed.

As the new orientations are captured by the image capturing module **802a**, the orientation module **806** determines the new orientations of the image **602** and the display module **810a** displays the unit of content **204** in orientations corresponding to the new orientations of the image **602**.

In certain embodiments, the image capturing module **802a** of the mobile computing device **120** and/or the image capturing module **802b** of the computer **812** may also capture an environment surrounding the image **602**. In such an embodiment, the display module **810a** of the mobile computing device **120** and/or the display module **810b** of the computer **812** may display the environment surrounding the image with the unit of content **204** superimposed on the environment surrounding the image **602**.

For example, FIG. **10** illustrates a schematic block diagram illustrating one embodiment of an operation **1000** of the image capturing module **802** and the display module **810a** for superimposing a unit of content **204** on a capture of an environment **1002** surrounding an image **602**. In certain embodiments, the image capturing module **802** captures a rendering of an environment **1002** surrounding an image **602** or a portion **604** of an image **602**. If the image **602** or portion **604** of the image **602** includes embedded cryptographic representations **302** for each character **212** of the code **202**, the decoding module **804** decodes the embedded cryptographic representations **302** of the characters **212** in the code **202** and the content retrieval module **808** retrieves the unit of content **204** corresponding to the code **202**.

The display module **810a** displays the environment **1002** surrounding the image **602** and overlays the unit of content **204** on top of the environment surrounding the image **602**. Thus, in certain embodiments, the unit of content **204** appears to be emanating from the environment surrounding the image **602**. In one embodiment, the orientation module **806** may determine the orientation of the image **602** and the display module **810a** may display the unit of content **204** in an orientation corresponding to the orientation of the image **602**.

The embodiments discussed above with reference to FIGS. **9A**, **9B** and **10** reference the image capturing module **802a** and the display module **810a** of the mobile computing device **120**. However, one of skill in the art will recognize that the

19

operations **900**, **910**, and **1000** of **9A**, **9B** and **10** may be performed with the image capturing module **802b** and the display module **810b** of the computer **812**.

FIG. **11** is a schematic block diagram illustrating another embodiment of an apparatus **1100** to communicate content in accordance with the present invention. In certain embodiments, the apparatus **800** includes an image capturing module **802**, a decoding module **804**, an orientation module **806**, a content retrieval module **808**, and a display module **810**.

In certain embodiments, the image capturing module **802** captures a live video of an image **1102** and an environment surrounding the image **1102**. The image **1102** includes an embedded cryptographic representation **302** of a code **202**. The embedded cryptographic representation **302** of the code **202** and the code **202** itself are discussed above. In the embodiment illustrated in FIG. **11**, the image capturing module **802** has captured a live video of a business card **1106** and the environment surrounding the business card **1106**.

If the orientation of the image **1102** is altered with respect to the image capturing module **802**, the display module **810** displays the live video of the image **1102** in the altered orientation. For example, FIG. **11** depicts the business card **1106** in a first orientation **1108** and a second orientation **1110**. In the first orientation **1108**, the business card **1106** is oriented in a substantially flat orientation with the top portion **1112** of the business card **1106** being substantially the same distance from the image capturing module **802** as the bottom portion **1114** of the business card **1106**. In the second orientation **1110**, the top portion **1112** is positioned further away from the image capturing module **802** than the bottom portion **1114**.

The display module **810** displays a live video of the image **1102** (the business card **1106**). Accordingly, as the orientation of the image **1102** changes, the display module **810** displays the image **1102** in the various new orientations.

In certain embodiments, the decoding module **804** decodes the embedded cryptographic representation **302** of the code **202** to determine the code **202**. The code **202** corresponds to a unit of content **204** such as an image **206**, a video image **208**, a webpage **210**, etc. In the embodiment illustrated in FIG. **11**, the unit of content **204** is depicted as a three dimensional video image **208**, in this case a three dimensional video image of a frog **1104**.

Typically the embedded cryptographic representation **302** of the code **202** is difficult to detect in the image **1102**. In certain embodiment, the embedded cryptographic representation **302** of the code **202** in the image **1102** is undetectable by a human but can be detected by electronic means. In the embodiment illustrated in FIG. **11**, the embedded cryptographic representation **302** of the code **202** in the image **1102** is depicted as being unobservable by a human (i.e., the embedded cryptographic representation **302** of the code **202** is not illustrated in FIG. **11**). However, one of skill in the art will recognize that in certain embodiments, the cryptographic representation **302** of the code **202** is included in the image **1102** and is observable by a computer implemented mechanism. For example, in one embodiment, the cryptographic representation **302** of the code **202** is included in the image **1102** in a single color channel (i.e., a blue color channel) which, when observed by a human is difficult or impossible to detect. In other embodiments, the cryptographic representation **302** of the code **202** may be observable in the image **1102** by a human upon close inspection but remains relatively unobservable upon casual inspection.

The decoding module **804** decodes the embedded cryptographic representation **302** of the code **202** to determine the code **202**. The content retrieval module **808** uses the code **202**, as determined by the decoding module **804**, to retrieve the

20

unit of content **204** (the three dimensional video image of the frog **1104**) from a storage location. In certain embodiments, the unit of content **204** may be stored on a hard drive on a server. In other embodiments, the unit of content **204** may be stored on a hard drive of another computer accessible through a computer network such as computer network **110**. One of skill in the art will recognize that the unit of content **204** may be stored on any storage device accessible by the mobile computing device **120** or the computer **812**.

The display module **810** displays the live video of the image **1102** (the business card **1106**). In one embodiment, the display module **810** also displays the unit of content **204** on the live video of image **1102** and/or the environment surrounding the image **1102**. Thus, rather than directing a web browser to a website hosting the unit of content **204** and displaying the unit of content **204** within the web browser, the unit of content **204** is displayed directly in the display module **810** overlaying the image **1102** and/or the image **1102** environment. For example, in the embodiment illustrated in FIG. **11**, the three dimensional video image of the frog **1104** is retrieved from the storage location and displayed on the live video image **1102** of the business card **1106**. Because the video image of the frog **1104** is three dimensional, the frog appears to be standing on the video image **1102** of the business card **1106**.

In certain embodiments, the apparatus **1100** includes an orientation module **806** that determines the orientation of the image **1102** (i.e., the business card **1106**). In such an embodiment, the display module **810** displays the unit of content **204** (i.e., the video image of the frog **1104**) in an orientation corresponding to the orientation of the image **1102**. If the image **1102** (the business card **1106**) is rotated to another orientation, the video image of the frog **1104** changes such that the frog appears to be standing on the business card **1106** in the different orientation. In certain embodiments, the display module **810** displays the unit of content **204** (the video image of the frog **1104**) on the live video of the image **1102**, with the unit of content **204** extending from the video image **1102** in three dimensions.

In one embodiment, the video image of the frog **1104** only includes image data for the frog (and any associated accessories held by the frog such as the cell phone illustrated in FIG. **11**) and does not include any background image data. In such an embodiment, only the frog (and any associated accessories held by the frog) is shown as being overlaid on the video image **1102** of the business card **1106**. In other embodiments, the frog may be shown in a virtual environment with the frog and the virtual environment overlaid on the video of the image **1102**.

FIG. **12** is a schematic block diagram illustrating another embodiment of an apparatus **1200** to communicate content in accordance with the present invention. In certain embodiments, the apparatus **800** includes an image capturing module **802**, a decoding module **804**, a content retrieval module **808**, and a display module **810**.

In certain embodiments, the image capturing module **802** captures a rendering of at least a portion of a first still image **1202**. In such an embodiment, the first still image **1202** may be a shot from a sequence of images of a video **1204**. For example, in the embodiment illustrated in FIG. **12**, the first still image **1202** is depicted as a still image of a golfer **1208** with the golf club positioned at the pinnacle of the golfer's **1208** golf swing. The sequence of images of the video **1204** include a series of still images that make up a video **1204** of the golfer **1208** finishing the golf swing.

The first still image **1202** includes an embedded cryptographic representation **302** of a code **202** with the code **202**

21

corresponding to the sequence of still images that make up the video **1204**. The decoding module **804** decodes the embedded cryptographic representation **302** of the code **202** to identify the code **202**. The content retrieval module **808** retrieves the sequence of still images of the video **1204** corresponding to the code **202**, in this embodiment, the still images that make up the video **1204** of the golfer **1208** finishing the golf swing.

The display module **810** displays the sequence of still images of the video **1204**. In certain embodiments, the first displayed shot of the video **1204** is the first still image **1202**. The remainder of the video **1204** includes the remaining series of images from the sequence of images of the video **1204** displayed in chronological order. Thus, in one embodiment, the display module **810** displays the first still image **1202** first with the remainder of the still images of the golf swing being displayed in chronological order thereafter. In such an embodiment, the first still image **1202** appears to come alive such that the golfer **1208** appears to finish the golf swing.

In certain embodiments, the display module **810** automatically displays the sequence of still images of the video **1204** in response to the decoding module **804** decoding the embedded cryptographic representation **302** of the code **202** and the content retrieval module **808** retrieving the sequence of still images of the video **1204** corresponding to the code **202**. Thus, when an image **1202** having an embedded cryptographic representation **302** of a code **202** is positioned within the view of the image capturing module **802**, the display module **810** displays a video **1204** of the image **1202** beginning at the point in time at which the image **1202** was captured.

While the embodiment illustrated in FIG. **12** depicts a video of a golfer **1208** completing a golf swing, one of skill in the art will recognize that the apparatus **1200** may be used with any series of images that make up a video **1204** to make a single still image **1202** appear to come alive. For example, in one embodiment, the single still image **1202** may be a still of a bride in a photo shoot and the apparatus **1200** may appear to make the bride come alive to finish the photo shoot. In other embodiments, the single still image **1202** may be a magazine advertisement for an automobile, wherein the automobile "comes alive" to show the performance characteristics of the automobile. In yet another embodiment, the apparatus **1200** may be used to make any still image **1202** appear to "come alive."

FIG. **13** illustrates a schematic flowchart diagram of a method **1300** of embedding information in an image **602** according to one embodiment of the present invention. In certain embodiments, the method **1300** may be performed using the system **100** described above.

The method **1300** begins **1302** and the code definition module **104** defines **1304** a code **202** corresponding to a unit of content **204**. As discussed above, the code **202** includes at least one character **212**. The cryptography module **106** defines a cryptographic representation **302** for each character **212** of the at least one character **212** in the code **202**.

Each cryptographic representation **302** includes a group **504** of regularly spaced mark locations **304**. Each mark location **304** includes a mark selected from one of a nonnative mark and a native mark. A pattern of marks in the group **504** of regularly spaced mark locations **304** is unique to each character **212** of the at least one character **212** in the code **202**.

In one embodiment, the embedding module **108** embeds **1308** the cryptographic representation **302** for each character **212** of the at least one character **212** of the code **202** into at least a portion of an image **602**, with the distance between

22

mark locations **304** in the image **602** indicate an orientation of the image **602** and the method ends **1310**.

In one embodiment, the method **1300** also includes determining an orientation of the image **602** having the embedded cryptographic representations **302** by comparing a distance **702** between mark locations **304** in a first group **504** of regularly spaced mark locations with a distance **702** between mark locations **304** in a second group **504** of regularly spaced mark locations **304**. In such an embodiment, the distance **702** between mark locations **304** in the various groups **504** indicates an orientation of the image **602**. In other embodiments, the orientation module **109** may compare the sizes of markings contained within the mark locations **304** to determine the orientation of the image **602**.

FIG. **14** is a schematic flowchart diagram illustrating one embodiment of a method **1400** to communicate content in accordance with the present invention. In certain embodiments, the method **1400** may be performed using the apparatus **800** described above.

The method **1400** begins **1402** and the image capturing module **802** captures **1404** a rendering of at least a portion **604** of an image **602** having an embedded cryptographic representation **302** of at least one character **212** in a code **202**. The code **202** corresponds to a unit of content **204**. The embedded cryptographic representation **302** of the characters **212** identifies an orientation of the at least a portion **604** of the image **602**.

The decoding module **804** decodes **1406** the embedded cryptographic representations **302** of the characters **212** in the code **202**. The orientation module **806** determines **1408** an orientation of the rendering of the image **602**. The content retrieval module **808** retrieves **1410** the unit of content **204** corresponding to the code **202** from a storage location and the display module **810** displays **1412** unit of content **204** in an orientation corresponding to the orientation of the rendering of the image **602**. The method **1400** then ends **1414**.

The above described systems, apparatus and methods may be particularly useful in a marketing program. For example, in certain embodiments, any image **602** may be embedded with cryptographic representations **302** of a code **202**. In an exemplary embodiment, the cryptographic representations **302** of the code **202** may be embedded into images **602** used as logos, advertisements, magazine articles, etc. Because the code **202** is linked or otherwise identifies a particular unit of content **204**, the image **602** may be used to retrieve that unit of content **204**. The unit of content **204** may then be displayed to the user to provide additional information about the image owner's products or services. One of skill in the art will recognize that the present invention may be useful in any arena where an individual would like to convey information in a limited space (i.e. in an image **602**).

FIG. **15** is a schematic flowchart diagram illustrating one embodiment of a method **1500** to capture live video of an image with embedded code to access and communicate content in accordance with the present invention. The method **1500** begins **1502** and captures **1504** a live video of an image and an environment surrounding the image. The image has an embedded cryptographic representation of a code where the code corresponds to a unit of content. The method **1500** may also determine (not shown) an orientation of the image. In one embodiment, the embedded cryptographic representation of the at least one character identifies an orientation of the at least a portion of the image.

The method **1500** decodes **1506** the embedded cryptographic representation of the code and retrieves **1508** the unit of content corresponding to the code from a storage location. The method **1500** displays **1510** the unit of content on the live

23

video of the image and/or the image environment, and the method **1500** ends **1512**. The unit of content may be a video, an image, or other type of image.

FIG. **16** is a schematic flowchart diagram illustrating one embodiment of a method **1600** to capture a rendering of a still image with embedded code to access and communicate a sequence of related still images in accordance with the present invention. The method **1600** begins **1602** and captures **1604** a rendering of at least a portion of a first still image. The first still image includes a shot from a sequence of images of a video. The first still image has an embedded cryptographic representation of a code where the code corresponds to the sequence of still images comprising the video.

The method **1600** decodes **1606** the embedded cryptographic representation of the code to identify the code and retrieves **1608** the sequence of still images of the video corresponding to the code. The method **1600** displays **1610** the sequence of still images of the video, and the method **1600** ends **1612**. A first displayed shot of the video includes the first still image and a remainder of the video includes a remaining series of images from the sequence of images of the video displayed in chronological order. In one embodiment, displaying **1610** the sequence of still images of the video includes automatically displaying the sequence of still images of the video in response to decoding **1606** the embedded cryptographic representation of the code and retrieving **1608** the sequence of still images of the video corresponding to the code.

The present invention may be embodied in other specific forms without departing from its spirit or essential characteristics. The described embodiments are to be considered in all respects only as illustrative and not restrictive. The scope of the invention is, therefore, indicated by the appended claims rather than by the foregoing description. All changes which come within the meaning and range of equivalency of the claims are to be embraced within their scope.

What is claimed is:

1. An apparatus to communicate content, the apparatus comprising:
  - an image capturing module that captures a rendering of at least a portion of a first still image, the first still image comprising a shot from a sequence of images of a video, the first still image having an embedded cryptographic representation of a code, the code corresponding to the sequence of still images comprising the video, the image capturing module capturing the rendering of the at least a portion of the first still image through a camera focused on the first still image;
  - a decoding module that decodes the embedded cryptographic representation of the code to identify the code;
  - a content retrieval module that retrieves the sequence of still images of the video corresponding to the code;
  - a display module that displays the sequence of still images of the video, wherein a first displayed shot of the video comprises the first still image, wherein a remainder of the video comprises a remaining series of images from the sequence of images of the video displayed in chronological order; and
  - an orientation module that determines an orientation of the rendering of the at least a portion of the still image, wherein the display module changes the displayed orientation of the sequence of still images in response to the orientation module determining that the orientation of the rendering of at least a portion of the still image has changed,

24

wherein said modules comprise one or more of hardware and program code, the program code stored on one or more non-transitory, tangible computer readable storage media.

2. The apparatus of claim 1, wherein the display module automatically displays the sequence of still images of the video in response to the decoding module decoding the embedded cryptographic representation of the code and the content retrieval module retrieving the sequence of still images of the video corresponding to the code.

3. The apparatus of claim 1, wherein each cryptographic representation of each character of the code comprises a group of regularly spaced mark locations, each mark location having a mark selected from one of a nonnative mark and a native mark, wherein a pattern of marks in the group of regularly spaced mark locations is unique to each character in the code.

4. The apparatus of claim 3, further comprising an orientation module that determines an orientation of the rendering of the at least a portion of the still image, wherein orientation of the rendering of the at least a portion of the still image is determined by comparing a distance between mark locations in a first group of regularly spaced mark locations with a distance between mark locations in a second group of regularly spaced mark locations.

5. The apparatus of claim 4, wherein the orientation of the rendering of at least a portion of the still image is determined in three dimensions.

6. The apparatus of claim 3, wherein the nonnative mark comprises a marking added to the still image, the marking having a perceptible difference between a native intensity value of a location in the still image and an intensity value of the marking added to the still image.

7. The apparatus of claim 6, wherein the perceptible difference between the native intensity value of the location in the still image and the intensity value of the marking added to the still image comprises a difference that is greater than a predefined threshold.

8. The apparatus of claim 1, wherein the image capturing module captures an environment surrounding the at least a portion of the still image, wherein the display module displays the environment surrounding the at least a portion of the still image, wherein the sequence of still images is superimposed on the environment surrounding the at least a portion of the still image.

9. The apparatus of claim 1, further comprising a mobile device, the mobile device comprising the image capturing module, the decoding module, the content retrieval module, and the display module.

10. A method for communicating content, the method comprising:

capturing a rendering of at least a portion of a first still image, the first still image comprising a shot from a sequence of images of a video, the first still image having an embedded cryptographic representation of a code, the code corresponding to the sequence of still images comprising the video, wherein capturing the rendering of the at least a portion of the first still image is through a camera focused on the first still image;

decoding the embedded cryptographic representation of the code to identify the code;

retrieving the sequence of still images of the video corresponding to the code; and

displaying the sequence of still images of the video, wherein a first displayed shot of the video comprises the first still image, wherein a remainder of the video com-

25

prises a remaining series of images from the sequence of images of the video displayed in chronological order; and

determining an orientation of the rendering of the at least a portion of the still image and adjusting the displayed orientation of the sequence of still images in response to the determining that the orientation of the rendering of at least a portion of the still image has changed.

11. The method of claim 10, wherein displaying the sequence of still images of the video comprises automatically displaying the sequence of still images of the video in response to decoding the embedded cryptographic representation of the code and retrieving the sequence of still images of the video corresponding to the code.

12. The method of claim 10, wherein each cryptographic representation of each character of the code comprises a group of regularly spaced mark locations, each mark location having a mark selected from one of a nonnative mark and a native mark, wherein a pattern of marks in the group of regularly spaced mark locations is unique to each character in the code.

13. The method of claim 12, wherein orientation of the rendering of the at least a portion of the still image is determined by comparing a distance between mark locations in a first group of regularly spaced mark locations with a distance between mark locations in a second group of regularly spaced mark locations.

14. The method of claim 10, wherein displaying the sequence of still images of the video comprises changing the displayed orientation of the sequence of still images in response to determining that the orientation of the rendering of at least a portion of the still image has changed.

15. The method of claim 12, wherein the nonnative mark comprises a marking added to the still image, the marking having a perceptible difference between a native intensity value of a location in the still image and an intensity value of the marking added to the still image.

16. The method of claim 10, wherein capturing a rendering of at least a portion of a first still image comprises capturing an environment surrounding the at least a portion of the still image, wherein displaying the sequence of still images of the video comprises displaying the environment surrounding the at least a portion of the still image, wherein the sequence of still images is superimposed on the environment surrounding the at least a portion of the still image.

17. A computer program product for displaying content, the computer program product comprising a non-transitory

26

computer readable storage medium having program code embodied therein, the program code executable by a processor for:

capturing a rendering of at least a portion of a first still image, the first still image comprising a shot from a sequence of images of a video, the first still image having an embedded cryptographic representation of a code, the code corresponding to the sequence of still images comprising the video, wherein capturing the rendering of the at least a portion of the first still image is through a camera focused on the first still image;

decoding the embedded cryptographic representation of the code to identify the code;

retrieving the sequence of still images of the video corresponding to the code; and

displaying the sequence of still images of the video, wherein a first displayed shot of the video comprises the first still image, wherein a remainder of the video comprises a remaining series of images from the sequence of images of the video displayed in chronological order; and

wherein capturing a rendering of at least a portion of a first still image comprises capturing an environment surrounding the at least a portion of the still image, wherein displaying the sequence of still images of the video comprises displaying the environment surrounding the at least a portion of the still image, wherein the sequence of still images is superimposed on the environment surrounding the at least a portion of the still image.

18. The computer program product of claim 17, wherein displaying the sequence of still images of the video comprises automatically displaying the sequence of still images of the video in response to decoding the embedded cryptographic representation of the code and retrieving the sequence of still images of the video corresponding to the code.

19. The computer program product of claim 17, further comprising determining an orientation of the rendering of the at least a portion of the still image and adjusting the displayed orientation of the sequence of still images in response to the determining that the orientation of the rendering of at least a portion of the still image has changed.

20. The computer program product of claim 17, wherein each cryptographic representation of each character of the code comprises a group of regularly spaced mark locations, each mark location having a mark selected from one of a nonnative mark and a native mark, wherein a pattern of marks in the group of regularly spaced mark locations is unique to each character in the code.
